

# 1. Iterator

## 1.1 The Essence of an Iterator

An iterator is a **unified traversal interface**.

## 1.2 Key Methods for Using Iterators in Different Classes

### Common container-side interfaces

- `begin()` : returns the starting iterator
- `end()` : returns the ending iterator (the position **one past the last element**)

### Common iterator-side interfaces

- `operator++()` : advance to the next element
- `operator==()` : check whether two iterators are equal
- `operator!=()` : check whether two iterators are not equal
- `operator*()` : dereference and get the element at the current position
- `operator->()` : access a member of the current element

### Standard traversal template

**stlList.cpp**

```
1 #include <list>
2 #include <string>
3 #include <iostream>
4
5 struct Animal {
6     std::string name, food;
7     bool big;
8     Animal(std::string name = "blob", std::string food = "you", bool big = true) ;
9     name(name), food(food), big(big) { /* none */ }
10 }
11
12 int main() {
13     Animal g("giraffe", "leaves", true), p("penguin", "fish", false), b("bear");
14     std::list<Animal> zoo;
15
16     zoo.push_back(g);
17     zoo.push_back(p); // std::list's insertAtEnd
18     zoo.push_back(b);
19
20     for ( std::list<Animal>::iterator it = zoo.begin(); it != zoo.end(); it++ ) {
21         std::cout << (*it).name << " " << (*it).food << std::endl;
22     }
23
24     return 0;
25 }
```

*Handwritten notes:*

- `Animal()`; `Animal(name, food);`
- `Animal(string name);` `Animal(....);`
- `std::list<Animal>` → *type*
- `std::list<Animal>::iterator` → *indirection*
- `it` → *animal*
- `it != zoo.end()` → *name*
- `it++` → *giraffe leaves*  
*penguin fish*

## 1.3 (\*it).x VS it->x

If an iterator points to an object, these two forms are usually equivalent:

- (\*it).x
- it->x

Be careful with operator precedence:

- . has higher precedence than \*
- So \*it.name is wrong

You must write:

- (\*it).name

## 1.4 Implementing a Customized Iterator

### Queue.h

```
4 template <class QE>
5 class Queue {
6     public:
7         class QueueIterator : public std::iterator<std::bidirectional_iterator_tag, T> {
8             public:
9                 QueueIterator(unsigned index);
10                QueueIterator& operator++();
11                bool operator==(const QueueIterator &other);
12                bool operator!=(const QueueIterator &other);
13                QE& operator*();
14                QE* operator->();
15            private:
16                unsigned location_ ;
17        }
18
19
20
21
22    private:
23        QE* arr_ ; unsigned capacity_, count_, entry_, exit_;
24
25        Array based.
26 };;
```

Access to location in the data structure.

```

1 #include <Queue.h>
2 #include <string>
3 #include <iostream>
4
5 struct Animal {
6     std::string name, food;
7     bool big;
8     Animal(std::string name = "blob", std::string food = "you", bool big = true) :
9         name(name), food(food), big(big) { /* none */ }
10 }
11
12 int main() {
13     Animal g("giraffe", "leaves", true), p("penguin", "fish", false), b("bear");
14     Queue<Animal> zoo;
15
16     zoo.push_back(g);
17     zoo.push_back(p);
18     zoo.push_back(b);
19
20     for ( Queue<Animal>::QueueIterator it = zoo.begin(); it != zoo.end(); it++ ) {
21         std::cout << (*it).name << " " << (*it).food << std::endl;
22     }
23
24     return 0;
25 }

```

## 2. Recursion

### 2.1 Basic Idea of Recursion

Recursion means:

- A function directly or indirectly calls itself.

For recursion to work, it must contain two parts:

#### Base case

The smallest problem, answered directly without further self-calls.

#### Recursive case

Reduce the current problem into a smaller problem of the same type, then call itself to solve it.

## 2.2 Two Core Rules of Recursion

**Rule 1: There must be a base case**

**Rule 2: Every recursive call must get closer to the base case**

## 2.3 Implementing Simple Recursive Functions

### Example 1: Factorial

```
int fact(int n) {  
    if (n == 0) return 1;  
    return n * fact(n - 1);  
}
```

## 3. List Array

### 3.1 Run Time

| Operation             | Unsorted Array List | Sorted Array List |
|-----------------------|---------------------|-------------------|
| insertAtFront         | $O(1)$              | $O(1)$            |
| insertAtIndex(i)      | $O(n)$              | $O(n)$            |
| removeAtIndex(i)      | $O(n)$              | $O(n)$            |
| insertAfterElement(x) | $O(n)$              | $O(n)$            |
| removeAfterElement(x) | $O(n)$              | $O(n)$            |
| findIndex(i)          | $O(1)$              | $O(1)$            |
| findData(x)           | $O(n)$              | $O(\log n)$       |

insertAtFront :

We need to consider the resize case, for both unsorted and sorted array,  $O(1)$ .

insertAtIndex(i) :

- unsorted: find:  $O(1)$ , move:  $O(n)$
- sorted: find:  $O(1)$ , move:  $O(n)$

removeAtIndex(i) :

- unsorted: find:  $O(1)$ , move:  $O(n)$
- sorted: find:  $O(1)$ , move:  $O(n)$

insertAfterElement(x) :

- unsorted: find:  $O(n)$ , move:  $O(n)$
- sorted: find:  $<O(n)$ , move:  $O(n)$

removeAfterElement(x) :

- unsorted: find:  $O(n)$ , move:  $O(n)$
- sorted: find:  $<O(n)$ , move:  $O(n)$

## 3.2 Resize Strategy

**Resize Strategy – when full, double the size**

$T(k) = \sum_{i=0}^{k-1} 2^i = 2^k - 1$   
 $= 2^{\lg(n)} - 1$   
 $= n - 1 = O(n)$

per insertion:  $O(1)$   
Amortized  $\Downarrow$   
constant insertion time

$n = 2^k \Rightarrow k = \lg(n)$

# 4. Linked List

## 4.1 Run Time

| Operation             | Unsorted Linked List | Sorted Linked List |
|-----------------------|----------------------|--------------------|
| insertAtFront         | $O(1)$               | $O(1)$             |
| insertAtIndex(i)      | $O(n)$               | $O(n)$             |
| removeAtIndex(i)      | $O(n)$               | $O(n)$             |
| insertAfterElement(x) | $O(n)$               | $O(n)$             |
| removeAfterElement(x) | $O(n)$               | $O(n)$             |
| findIndex(i)          | $O(n)$               | $O(n)$             |
| findData(x)           | $O(n)$               | worst $O(n)$       |

insertAtFront :

```
newNode->next = head;  
head = newNode;
```

insertAtIndex(i) :

- Finding the position:  $O(n)$
- Linking itself:  $O(1)$
- Total:  $O(n)$

removeAtIndex(i) :

- Finding the position:  $O(n)$
- Remove:  $O(1)$
- Total:  $O(n)$

```
prev->next = target->next;
```

insertAfterElement(x) :

- Search:  $O(n)$

- Link insertion:  $O(1)$
- Total:  $O(n)$

`removeAfterElement(x)` :

- Find target element:  $O(n)$
- Delete successor:  $O(1)$
- Total:  $O(n)$
